Chapter 1

Introduction

1.1 Abstract

In today's information-rich world, scientific publications play a pivotal role in disseminating knowledge and advancing research across various disciplines. The exponential growth of digital repositories, such as arXiv, has made it increasingly challenging for researchers to keep up with the vast volume of available literature. To address this challenge, we propose a novel approach that harnesses the power of Kaggle datasets for arXiv paper topic classification and builds a robust recommendation system.

1.2 Introduction

The classification and recommendation of scientific papers have garnered significant attention in recent years as researchers strive to effectively navigate the ever-expanding realm of scholarly knowledge. The sheer volume of articles and the diverse range of topics covered make it essential to develop intelligent systems that can automate the classification process and provide targeted recommendations.

In this report, we present a comprehensive methodology that leverages Kaggle datasets, renowned for their quality and diversity, to tackle the task of arXiv paper topic classification. By exploiting the rich and multidimensional nature of these datasets, we aim to enhance the accuracy and scalability of our classification model. Furthermore, we utilize the outputs of this model to build a powerful recommendation system that assists researchers in discovering relevant papers within their areas of interest.

Multi-label classification forms the core of our approach, as it enables the assignment of multiple topic labels to individual papers, accommodating the intricate nature of scientific research. Through a combination of text mining techniques, machine learning algorithms, and natural language processing (NLP) methodologies, we strive to accurately classify papers based on their content, thereby allowing researchers to efficiently navigate and explore the vast corpus of arXiv publications.

Our proposed recommendation system enhances the traditional search-based approaches by considering the similarity between papers. By leveraging the knowledge gained from the multi-label

classification model, we can measure the semantic similarity between papers based on shared topics and concepts. This enables us to provide personalized recommendations, suggesting papers that are highly relevant to the research interests of individual users.

1.3 About Dataset

Data Source: <https://www.kaggle.com/datasets/Cornell-University/arxiv>

The dataset contains the following columns:

1. id : Arxiv ID
2. submitter: Who submitted the paper
3. authors: Authors of the paper
4. title: Title of the paper
5. comments: Additional info, such as number of pages and figures
6. journal-ref: Information about the journal the paper was published in
7. doi: Digital Object Identifier
8. abstract: The abstract of the paper
9. categories: Categories / tags in the ArXiv System
10. versions: A version history

Paper can be accessed directly using these links:

1. <https://arxiv.org/abs/id>: Page for this paper including its abstract and further links
2. <https://arxiv.org/pdf/id>: Direct link to download the PDF

1.4 Data Statistics

There are 176 unique labels for the paper in this dataset. The maximum published and minimum published as per the categories are as follow:

Maximum Published	No. of paper	Minimum Published	No. of paper
astro-ph	104928	bayes-an	16
quant-ph	136005	ao-sci	17
cs.LG	143500	plasm-ph	38
hep-th	158697	acc-phys	48
hep-ph	171480	atom-ph	123

Table 1.1: Maximum and minimum published label with no. of papers

The following figure shows the number of labels assigned to a paper. We can see one paper is assigned 13 labels which is the maximum number of labels in the whole dataset.

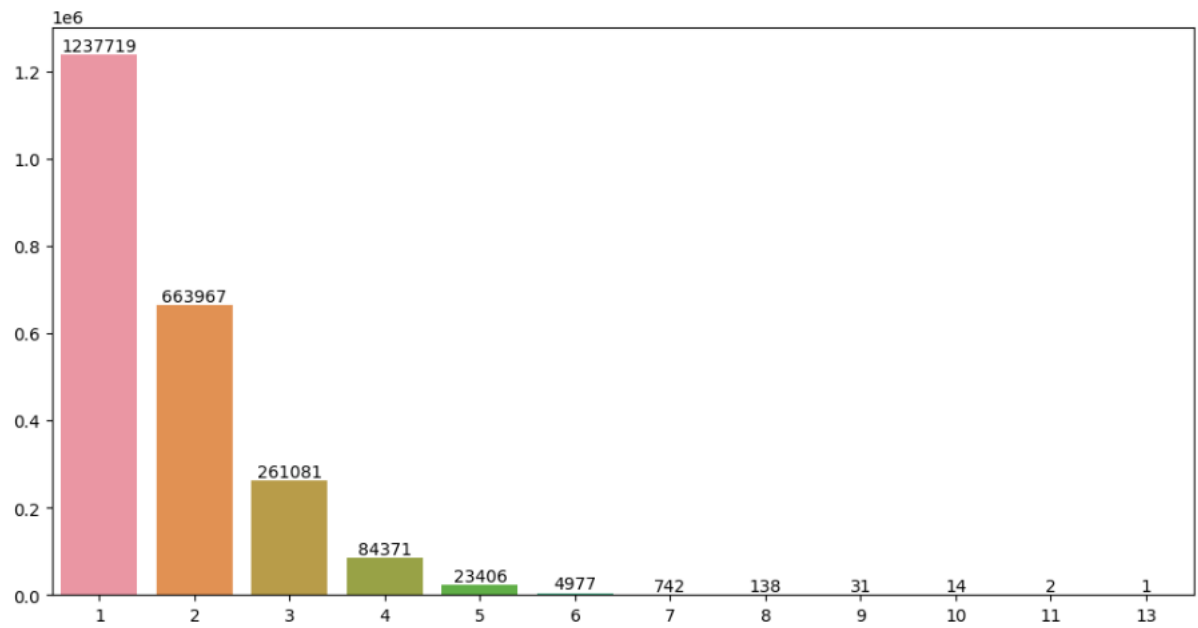

Figure 1.1: Categories Count Plot

1.5 Expected Outcome

We expect to assign label to the new paper based on the title and abstract of the given paper using the multi label classifier model.

Using recommendation system, user should be able to get the similar paper for the given paper.

Chapter 2

Project Management

2.1 Agile Development Methodology

Teams use the agile development methodology to minimize risk (such as bugs, cost overruns, and changing requirements) when adding new functionality. In all agile methods, teams develop the software in iterations that contain mini-increments of the new functionality. There are many different forms of the agile development method, including scrum, crystal, extreme programming (XP), and feature-driven development (FDD).

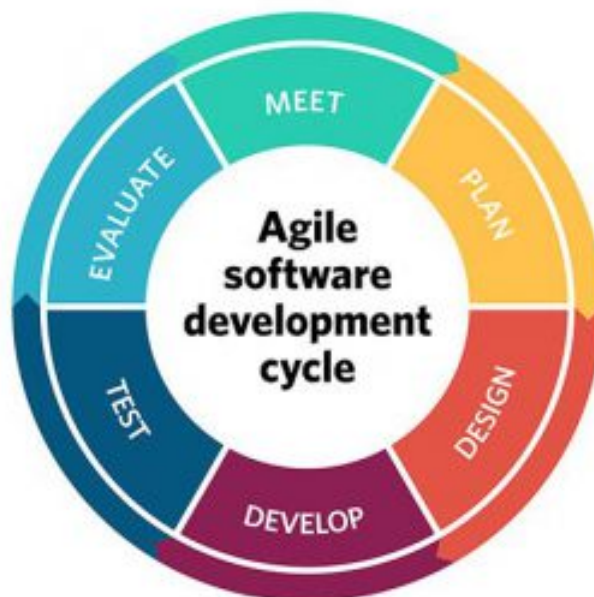

Figure 2.1: Agile Development Methodology

2.2 Trello

We are going to use Trello's default agile board for task management.

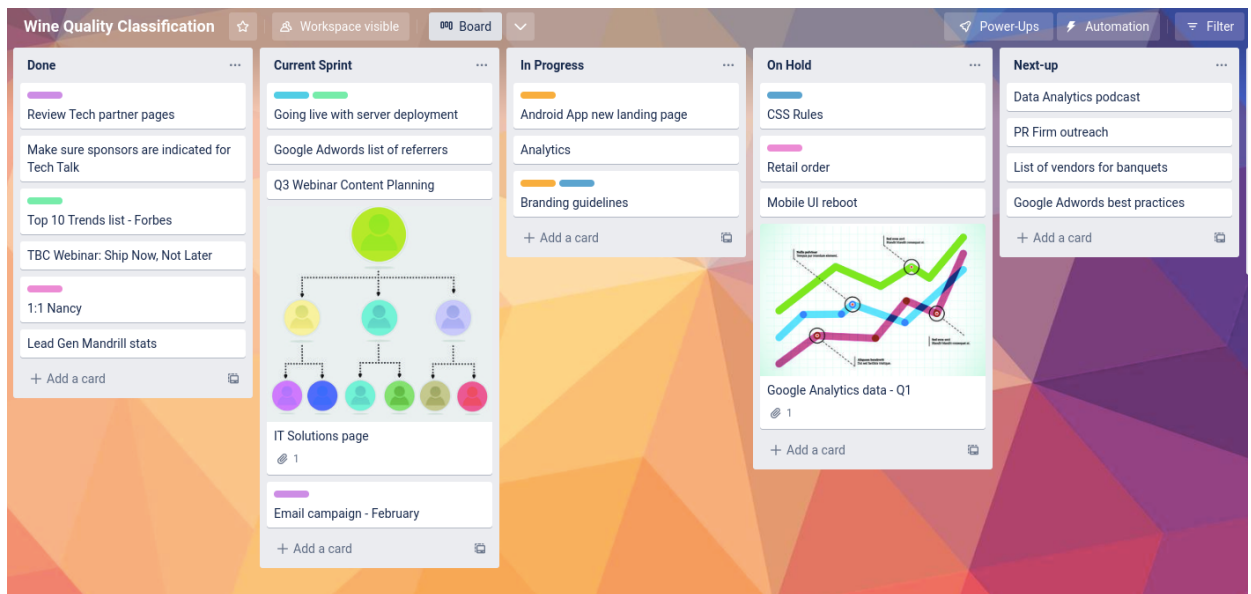

Figure 2.2: Trello

2.3 Discord

We are going to use Discord server for effective communication and team meetings.

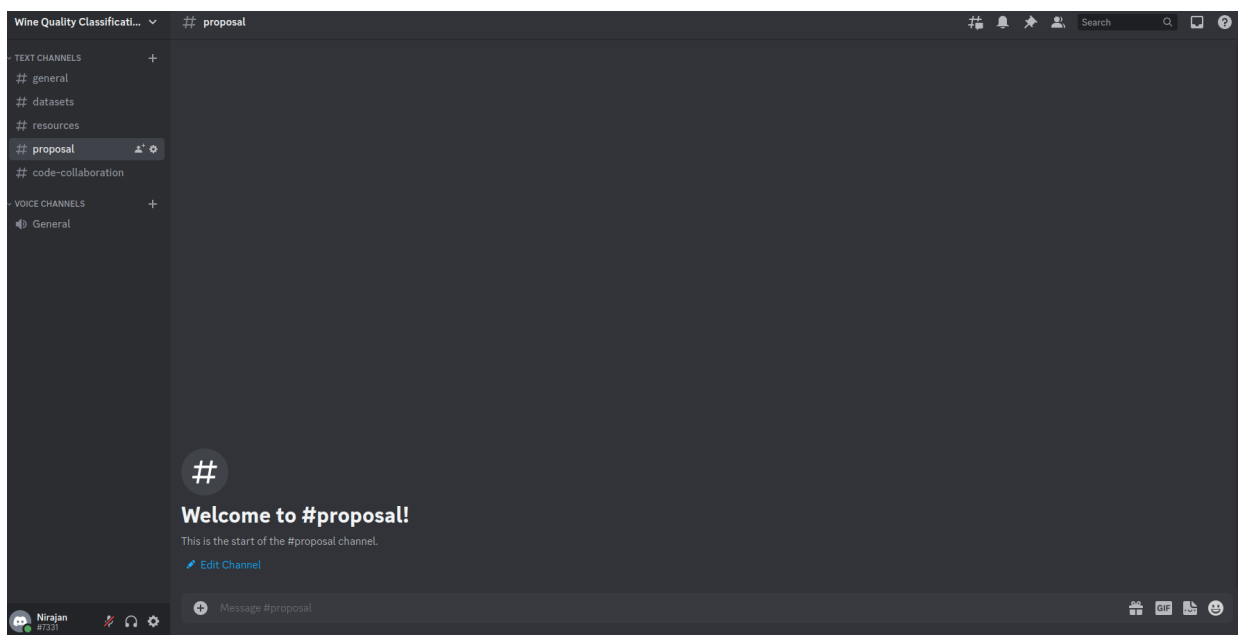

Figure 2.3: Discord

2.4 Tensorboard

Tensorboard will be used for experiment tracking.

Chapter 3

Model Development and Evaluation

3.1 Model Development

Model for the multi label classification can be developed using Embedding, LSTMs and Dense layers. Moreover, Transformer model can also be used for creating this classification model.

The recommendation system can be developed by taking the layer of dense layer as features of the paper and calculating the similarities between the paper. This can be used to recommend new paper given some input paper.

3.2 Model Evaluation

Various evaluation metrics like Hamming Loss, Subset Accuracy will be used for the multi label classification.

Since our data is highly imbalanced, Hamming Loss is suitable as the evaluation metrics.
